

Explaining the "Problem Logging changes in EditHistory" error message

In some situations the above error message may occur, as shown in the image below. When it does the system Administrator should update the UIDGenerator table.

Problem logging changes in EditHistory table

When new records are created in an Orix database a new value is pulled through from the UIDGenerator table. The details of this process are explained in the following help document:

[The UID Generator Framework table](#)

Please review this if you are not already familiar with how this process works.

If something happens which means that records are being added to an Orix App and the UID used is already present, Orix will automatically jump back to the UIDGenerator, and next the next UID. This means that the user will not see any obvious error, and all data will be posted as normal.

However to surface the problem so that an administrator can be aware of it, the error above is generated. This occurs because of the clash as Orix tries to make note of the newly added record in the EditHistory table, and finds that the ID is not the number it was expecting.

When an administrator sees this error message on a system they should immediately review the UIDGenerator table, and switch the UID range to one which is not in use in another system.
